1. Executive Summary

The California State Coastal Conservancy's San Francisco Estuary Invasive *Spartina* Project (ISP) implemented their 2024 Water Quality Monitoring Plan in conjunction with the treatment of non-native *Spartina* (cordgrasses). Water samples and data on conventional water quality parameters were collected pre-treatment, immediately after the herbicide application, and one-week post-treatment, in compliance with the Statewide General National Pollutant Discharge Elimination System (NPDES) Permit for Residual Aquatic Pesticide Discharges to Waters of the United States from Algae and Aquatic Weed Control Applications (Water Quality Order 2013-0002-DWQ). This report documents the water quality monitoring results from 2024 and compares them to the overall trends from ISP water quality monitoring since 2005.

Over the history of treatment implementation by the ISP Coalition partners, water sampling immediately after *Spartina* treatment has consistently found that any imazapyr concentrations detected in the receiving waters are two to four orders of magnitude below levels reported in the toxicology literature as a concern to humans or the animals that inhabit the associated tidal marsh system, including the benthic invertebrates that are fundamental to the tidal marsh food web. Pursuant to the Monitoring and Reporting Program outlined in the General NPDES Permit, the ISP Coalition was required to monitor one application site in 2024, since the results from monitoring six sites at the inception of the new permit in 2014 did not exceed the Monitoring Trigger for imazapyr established by the State Water Board. The imazapyr Monitoring Trigger is 11.2 mg/L, which is equivalent to 11,200 ppb. The ISP's measured imazapyr concentration sample for the 2024 treatment event was 0.18 ppb (0.0002 mg/L), more than 11,000 ppb *below* this Monitoring Trigger.

The successful *Spartina* control achieved by the ISP Coalition partners since 2005 has reduced the Estuary-wide infestation by 98% from 805 net acres to 18.7 net acres. With over 70% of historic sites either at Zero Detection or containing less than 10 m² net cover of invasive *Spartina* in 2024, most of the remaining infestations are so reduced that spot treatment by backpack or handheld sprayer is the only herbicide delivery system needed. The ISP is also completing the eradication of all infestations of *S. densiflora* around the Estuary with purely manual removal after achieving successful reductions with imazapyr over the initial years of the project. In 2024, 59 ISP sites were at the zero-detection level, showing continued progress towards the long-term goal of functional eradication.

The 2024 one-week post-treatment sampling result of 0.11 ppb continues to demonstrate that imazapyr is short-lived in an estuarine environment, which is consistent with the published literature. This imazapyr concentration reflects a 39% reduction from the treatment sample one week earlier, which was already a very low concentration. Substantial reductions after one week have not been uncommon for this project, as demonstrated by the 95.8% mean reduction in imazapyr that the ISP reported over the four-year span from 2007-2010. With the rapid degradation of this herbicide in the tidal environment, as measured by the imazapyr concentration detected in the water at the site one week after treatment, it is anticipated that sites that still had measurable concentrations at that point would likely be below detectable levels within a short time after that third sample.

The monitoring of conventional water quality parameters (water temperature, dissolved oxygen, pH, conductivity, salinity and turbidity) continued to demonstrate that there is no indication that the herbicide applications to invasive *Spartina* have had any impact on Estuary surface water quality; this result was entirely anticipated because there is no relevant pathway for the imazapyr treatment of an emergent plant to significantly alter these parameters in this vast open aquatic system with twice-daily tidal exchange of an enormous volume of water.

2. Introduction

2.1 Invasive *Spartina* in the San Francisco Estuary

The genus *Spartina* refers to cordgrasses, the majority of which are found in tidal salt marshes and sloughs, open mudflats, or brackish channels. Four species of non-native *Spartina* have been introduced to the San Francisco Estuary since the 1970s, and they spread aggressively (both vegetatively from underground rhizomes as well as by seed or vegetative propagules). *Spartina alterniflora* (smooth cordgrass) is native to the Atlantic and Gulf Coasts of the U.S. and was first introduced in 1976 by the U.S. Army Corps of Engineers as part of an experiment in tidal marsh restoration using dredge spoils at the Alameda Flood Control Channel. In the mid-1990s, researchers discovered that the introduced species had hybridized with our native Pacific cordgrass, *Spartina foliosa*, creating a fertile hybrid swarm with numerous morphologies and phenologies. These hybrids are the most problematic of the invaders, originally representing greater than 90% of the historical peak infestation of non-native *Spartina* that covered 805 net acres in 2005 but has been reduced by ISP partners by approximately 98%. The second most prevalent invader is *Spartina densiflora* (Chilean cordgrass), which was mistakenly introduced to Creekside Park along Corte Madera Creek in Marin County as part of a wetland restoration in the 1970s. The species spread throughout the Corte Madera Creek watershed and other eastern Marin wetlands, but it has had a very limited distribution elsewhere around the Bay. The other two species of introduced cordgrass that are approaching eradication, *S. anglica* (English cordgrass) and *S. patens* (salt meadow cordgrass), are each centered at only one marsh site in the Estuary and have not spread from those locations.

There are many potential impacts from these aggressive non-native *Spartina* species. Over the past 160 years, the development of the marshes of the San Francisco Estuary for homes and commercial interests had reduced the remaining marsh acreage by over 90%. The resulting habitat loss has contributed to reductions in the populations of several endangered tidal marsh species including the California Ridgway's rail (*Rallus obsoletus obsoletus*) and salt marsh harvest mouse (*Reithrodontomys raviventris*). Invasive *Spartina* further degrades the remnants of habitat by colonizing tidal channels used for foraging by rail, competitively excluding native marsh vegetation such as *Sarcocornia pacifica* (perennial pickleweed) that is important salt marsh harvest mouse habitat, and rare plants such as *Chloropyron molle* ssp. *molle* (soft bird's beak, formerly *Cordylanthus mollis* ssp. *mollis*), and by transforming unvegetated mudflats into *Spartina* meadows and thereby eliminating foraging areas for millions of migratory and resident shorebirds. The infestations of non-native *Spartina* also present direct problems to the human population beyond the loss of biodiversity and habitat. Flood control channel capacity can be severely reduced by *Spartina* expansion, not allowing

flood waters to be conveyed away from homes and businesses, and the resulting sediment accretion can significantly raise annual maintenance budgets for regular dredging. Dense stands of *Spartina* can also impound water and create ponded areas in the upper marsh that become excellent breeding areas for salt marsh mosquitoes.

2.2 Invasive *Spartina* Project

In response to the expanding infestation of non-native *Spartina*, the California State Coastal Conservancy and U.S. Fish & Wildlife Service formed the Invasive *Spartina* Project (ISP) in 2000 to coordinate a regional effort to arrest and reverse the spread of these aggressive invaders and eventually eradicate them from the Estuary. A major impetus for the effort was to protect the \$100 million investment to acquire salt ponds from Cargill that will be converted to marsh and other related habitat as part of the South Bay Salt Ponds Restoration (SBSP), the largest such effort on the West Coast of the United States. Virtually every San Francisco Estuary tidal restoration project over the past 35 years has been colonized, and its marsh development trajectory potentially compromised, by hybrid *Spartina*. The ISP is working to remove this threat from the Estuary so that SBSP and other tidal restoration efforts can proceed successfully.

After several years of compiling environmental documentation and permits, completing initial surveys of the Estuary shoreline, and implementing several pilot projects on control methods, the ISP began control efforts in 2004 and baywide treatment in 2005. The Programmatic Environmental Impact Report (PEIR) for the ISP found that for most sites, the use of aquatic herbicide was the most effective method and caused the lowest environmental impacts, especially when confronted with the dense monocultures covering 50-100 contiguous acres of marshland and mudflat that existed at the peak of the infestation. The ISP developed individual Site-Specific Plans for each of their 220 sub-areas, incorporating Integrated Pest Management (IPM) strategies that evaluate the biology of the target invader and the suite of appropriate control methods to determine the most effective combination to utilize over time.

Treatment is conducted by a Coalition of ISP partners around the Estuary, with management and assistance from the ISP, and typically funded at least in part by grants from the California State Coastal Conservancy. In 2019, there was a transfer of responsibility for a portion of the ISP Coalition sites from California Wildlife Foundation to California Invasive Plant Council (Cal-IPC), with the necessary Notice of Termination and new Notice of Applicability issued by the State Water Board. Current ISP Coalition partners include the following:

1. California Department of Parks and Recreation (WDID#s 2 49AP00029)
2. California Invasive Plant Council (WDID# 2 01AP00040)
3. East Bay Regional Parks District (WDID# 2 01AP00022)
4. City of Alameda (WDID# 2 01AP00015)
5. City of Palo Alto (WDID# 2 43AP00011)
6. Friends of Corte Madera Creek Watershed (WDID# 2 21AP00010)
7. San Mateo County Mosquito & Vector Control District (WDID# 2 41AP00023)

The number of sites and total area addressed by each ISP partner varies. **Appendix V** lists the ISP partner associated with each treatment site, and **Appendix VII** provides maps showing the location of treatment sites associated with each partner.

Treatment is timed to achieve the longest possible tidal exposure of the *Spartina* to allow the herbicide to penetrate the leaf cuticle, so it is not washed off by the incoming tides (referred to as “dry time”). Therefore, ISP partners usually begin treatment on a low or receding tide just after sunrise during the active growing season of the cordgrass from June through October or November. Several other key aspects are factored into the timing equation. According to the California Department of Pesticide Regulation (CDPR) and the ISP Conservation Measures from our Programmatic Environmental Impact Report, herbicide applications should be conducted when sustained winds are less than 10 mph. Hence, ISP partners emphasize the need to begin treatment at dawn on appropriate days because the afternoon winds may halt control efforts prematurely. In addition, many of the marshes infested with non-native *Spartina* are home to the endangered California Ridgway’s rail, so work is scheduled around their breeding season. This results in relatively narrow windows of opportunity each year to accomplish the work during the active growing season of the *Spartina* when treatment will be effective.

2.3 Herbicide Utilized for *Spartina* Control

ISP partners use the aquatic formulation of imazapyr (sold under the trade names Habitat® or Polaris™) for invasive *Spartina* treatment. These two formulations, approved for use in sensitive estuarine systems, are virtually identical and contain a solution of either 28.7% (Habitat®) or 27.7% (Polaris™) isopropylamine salt of imazapyr in water, with the remaining inert ingredients composed of a small amount of acidifier (probably acetic acid, but this proprietary trade secret is not disclosed on the label) as well as a blue dye.

Imazapyr is a non-selective herbicide that can effectively control monocots (e.g. grasses such as *Spartina*) as well as broadleaf plants (dicots). It is a systemic herbicide that normally enters through the foliage in tidal marsh applications, and is circulated (translocated) throughout the plant and down into the roots causing mortality of the entire plant or clone; this is in contrast to a “contact herbicide” that works only on the above-ground portion of the vegetation providing temporary, single season control of a perennial plant like *Spartina* but not translocating to the roots where it could produce full mortality of those structures as well. ISP partners do not use contact herbicide, only systemic formulations.

Imazapyr works by inhibiting the enzyme acetolactate synthase (ALS) required for the biosynthesis of the three branched-chain amino acids valine, leucine and isoleucine. The ALS pathway exists in plants, as well as microorganisms such as bacteria, fungi and algae. Animals do not produce these essential amino acids themselves, normally acquiring them by consuming plants, which is likely one reason for the low toxicity of imazapyr to animals. Although imazapyr does little to alter respiration, photosynthesis or lipid and protein synthesis in the target plant, it does inhibit the rate of DNA synthesis by 63% within 24 hours of treatment; this inhibition can be used as an indirect measure of cell division which relates directly to growth. To achieve the maximum herbicidal activity, imazapyr should be applied post-emergence when the target plants are growing vigorously and during weather conditions that allow for slow drying of the droplets. ISP partners have observed that treated *Spartina* plants remain green for a long period of time and can remain in an arrested state of

development for weeks before finally showing signs of impending mortality. Fortunately, seed production is eliminated by the inhibition of DNA synthesis if the application occurs early enough in the phenology of the *Spartina*, even if clear evidence of full mortality is still weeks away.

Prior to the California registration of the aquatic formulation of imazapyr in August 2005, chemical control of non-native *Spartina* San Francisco Bay was attempted exclusively with glyphosate. However, this tool yielded consistently poor results and was falling far short of outpacing the spread of the invader. This failure is probably a result of glyphosate's affinity for adsorbing to sediment, causing it to bind to silt and salt that are deposited on the *Spartina* by the tides, thereby rendering the herbicide inactive. The glyphosate is not able to penetrate the leaf cuticle and enter the plant where it could be systemically circulated.

Within the first treatment season after imazapyr was approved by the State of California in August 2005, 96% of the applications by ISP partners had transitioned away from glyphosate to the new tool, and this rose to 100% utilizing imazapyr by 2006. In the recent past, glyphosate has only been used by ISP partners on a single site (Southampton Marsh) as part of the IPM strategy for eradication of *S. patens*, which is part of a multi-species noxious weed project focused mainly on *Lepidium latifolium* at this State Parks site. Glyphosate was added to the tank mix for the *S. densiflora* application at Creekside Park in 2011 in an effort to enhance the efficacy on the small remaining plants by inhibiting synthesis of an additional three amino acids (over the three aliphatic amino acids inhibited by imazapyr). There was no apparent enhancement achieved from the addition of a second herbicide to the mix, so glyphosate was not utilized in future treatments of this type.

The aquatic herbicide formulation of imazapyr does not contain a surfactant; consequently, this is added to the tank mix from a short list of products that are approved for use in aquatic systems. Since the leaves of the target *Spartina* plants in turbid San Francisco Bay can be covered with depositional material, uptake of the herbicide by the plant is difficult to achieve and the use of a surfactant plays a vital role in the application process. Surfactants improve uptake and enhance efficacy by lowering the surface tension of liquids, thereby improving the spread of the liquid herbicide mixture over the leaf surface, increasing adherence of the formulation to the leaf (wetting) while reducing runoff, and enhancing the penetration of the leaf cuticle.

ISP partners have primarily used Liberate® (Loveland Industries) during recent treatment seasons, with a handful of applications employing Competitor® (Wilbur-Ellis). Liberate® is a natural lecithin-based (soybean) product and consequently is presumed to have rapid biodegradation; this product also acts as a drift retardant which aids in ISP aerial or high-pressure hose applications, has a relatively low toxicity to aquatic life, and has been highly effective on hybrid *Spartina*. Competitor® is a methylated seed oil (MSO) recommended for use with imazapyr by the original manufacturer (BASF); this product strikes a good balance by combining one of the lowest relative toxicities to aquatic life of the available surfactants while consistently yielding high efficacy results. A non-toxic blue marker dye (e.g. Turf Trax or similar) is also included in the tank mix for ground-based treatment to help the applicator get full coverage without re-treating, which helps reduce the amount of chemical entering the marsh environment.

Recent studies have raised concern over a group of surfactants containing nonylphenol ethoxylate due to their moderate toxicity and suspected endocrine disruption in fish and aquatic organisms. Consequently, the ISP partners do not use these nonylphenol products (such as R-11®, ProSpreader®) for invasive *Spartina* control, although they are commonly used by other vegetation managers and are known to perform well at improving herbicide efficacy.

2.4 NPDES Compliance

Application of herbicides to waters of the United States requires coverage under a National Pollutant Discharge Elimination System (NPDES) permit pursuant to Section 402 of the Clean Water Act (CWA). The State Water Resources Control Board adopted the Statewide General National Pollutant Discharge Elimination System (NPDES) Permit for Residual Aquatic Pesticide Discharges to Waters of the United States from Algae and Aquatic Weed Control Applications, Water Quality Order 2013-0002-DWQ, for the reissuance of General NPDES Permit CAG990005 in June 2013. Order 2013-0002-DWQ became effective on December 1, 2013. The new permit replaces the interim Statewide General NPDES permit (Water Quality Order No. 2001-12-DWQ) that was adopted in 2001.

The General Permit allows for the use of a small list of U.S. EPA-approved aquatic herbicides, including the aquatic formulations of imazapyr (e.g. Habitat®, Polaris®) and glyphosate (e.g. Roundup Custom®, Aquamaster®, Rodeo®). For constituents that do not have Ambient Water Quality Criteria, the Instantaneous Maximum Receiving Water Monitoring Trigger is based on one tenth of the lowest 50 Percent Lethal Concentration (LC₅₀) from U.S. EPA's *Ecotoxicity Database*. Currently, there is no State or U.S. EPA-based numeric objective or criteria for imazapyr, but the new General Permit establishes an imazapyr Monitoring Trigger of 11.2 mg/L. Interestingly, this concentration is an order of magnitude beyond the highest water sample analyzed for ISP over the history of the project. Since ISP partners do not use surfactants containing nonylphenol ethoxylate (e.g. R-11®, ProSpreader®) the ISP did not perform any chemical concentration analyses for these compounds.

Each ISP Coalition partner conducting treatment with herbicide has prepared and submitted a Notice of Intent (NOI) to comply with the terms of the General Permit and paid the appropriate invoiced state fees. The partners were listed in Section 2.2 of this report. **Appendix V** shows the sites associated with each ISP partner, and **Appendix VII** provides maps of the location of treatment sites for each partner.

The ISP prepared an Aquatic Pesticide Application Plan (APAP) on behalf of the Coalition partners, which includes the annual Water Quality Monitoring Plan (WQMP). ISP also collects water quality samples, sends them to Pacific Agricultural Laboratory for herbicide concentration analysis, collects standard water quality parameter data at each of those events, and prepares and submits annual reports to the RWQCB for compliance with the General Permit.

3. Water Quality Monitoring Plan

3.1 Aquatic Pesticide Application Plan

The Statewide General Permit requires the discharger to develop and implement an Aquatic Pesticide Application Plan (APAP). ISP revised its extensive programmatic APAP in 2014 to comply with the requirements of the new General Permit (pages 9-11); the APAP was submitted to the State Water Board on behalf of the Coalition and was posted for the 30-day comment period (no comments were received). Each ISP partner reviews and adopts the Coalition APAP, submits a completed Notice of Intent to Comply with the Terms of this General Permit (Notice of Intent, NOI) along with the invoiced annual fee to the Regional Water Board. ISP's Coalition APAP provides an in-depth description of the water body where treatment will occur (the San Francisco Estuary), including background on the ecology, natural processes affecting water quality, and a survey of the general sediment and water quality characteristics currently documented for the system. The four species of non-native cordgrass (*Spartina*) are described as well as the motivation for the control work and the project's control tolerances. The pros and cons of various treatment methods are evaluated (including the reasoning behind the need for herbicide use), and the types of aquatic herbicide and expected application rates are provided. Finally, all ISP sites are described including their location and the status of the *Spartina* infestation, and a map of treatment areas is provided for each partner.

The APAP includes a Water Quality Monitoring Plan (WQMP) that the ISP implements in the field during the *Spartina* treatment season. ISP contracted with San Francisco Estuary Institute (SFEI) to implement the WQMP at the start of the project but took over the responsibility in 2006. In accordance with the new General Permit requirements, six sites were monitored in the first year (2014). Since none of those sites had returned an imazapyr concentration above the Monitoring Trigger of 11.2 mg/L (equivalent to 11,200 ppb), moving forward the ISP Coalition was only required to monitor a single site in future years under the current General Permit.

3.2 Treatment Monitoring Site Selection

The ISP had historically selected the treatment sites to be sampled for NPDES at locations that are representative of the overall, baywide *Spartina* control effort and used the following four treatment site types as a guide:

- I. Tidal Marsh, Microtidal Marsh, Former Diked Bayland, Backbarrier Marsh
- II. Fringing Tidal Marsh, Mudflats, and Estuarine Beaches
- III. Major Tidal Slough, Creek or Flood Control Channel
- IV. Urbanized Rock, Rip-Rap, Docks, Ramps, etc.

Each year, the ISP tried to select a relatively even distribution of these marsh site types to be sampled for water quality, as well as sampling the range of herbicide delivery systems and marsh dynamics present in the work program. However, now only a single site is monitored each year pursuant to the requirements of the General Permit. Type IV infestation sites are usually very small, sparse, and adjacent to large bodies of water with constant flushing that will serve to quickly dilute any herbicide incidentally entering the water column, so this site

type is not considered as high a priority for sampling as they were the least likely of the sites to retain detectable levels of herbicide related to the application. In addition, effective treatment by ISP partners has greatly reduced the number of Type II sites with any significant amount of non-native *Spartina* remaining; these fringe marshes had often been accreted by hybrid *Spartina* on previously-unvegetated mudflat and responded particularly well to treatment, returning these areas back to their natural condition preferred by shorebirds for foraging. Site Type I has been considered the most likely to retain detectable levels of herbicide in the water column, so the sampling program was normally weighted slightly in this direction. All recent ISP WQMPs have been implemented on Type I or II sites.

3.3 Sampling Design, Procedures & Analysis

Sampling Design

The sampling events were intended to characterize the potential impacts involved with imazapyr applications relative to adjacent surface waters. Consistent with permit requirements, the monitoring program included background or pre-treatment sampling within the 24-hour period prior to herbicide application, treatment event sampling immediately following herbicide application, and post-treatment sampling one week after herbicide application. During background sample collection, the location was recorded using GPS to aid ISP staff in relocating the point for subsequent sampling events. The treatment event sample was collected immediately adjacent to the treatment area after sufficient time had elapsed such that treated water would have entered the adjacent area on the incoming tide. Since the standard protocol is for the ISP partners to treat *Spartina* on a low or receding tide (with little to no water present) when possible, application event samples are often taken 1-4 hours post-treatment when the tide had again flooded the site, but samples could sometimes be collected within a short period after the treatment crew had left the area if sufficient water was already present (e.g. in the bottom of an adjacent channel). Finally, the one-week post-treatment monitoring was conducted when sufficient water was present at the site on the seventh day after the application. It is standard for the lab to include blanks as part of their quality control, but the ISP also submits trip blanks to enhance quality assurance, one over the course of the abridged monitoring season now that only one site is monitored.

Field Sampling Procedures

The ISP has conducted its own water quality monitoring program since 2006, modeled after sampling procedures developed for the State Water Resources Control Board (SWRCB) APMP and outlined in the 2004 APMP Quality Assurance Program Plan (QAPP). Water samples were collected using a sampling rod and pre-cleaned amber glass 250 milliliter bottles. To collect the sample, the bottle was attached to the sampling rod with a clamp, extended out over the water at the application site, and lowered to approximately 50% of the water depth. When the bottle was filled it was pulled back out of the water and the cap was affixed to the mouth of the bottle. The sample was labeled in permanent ink with the sample ID number, date, time, and initials of the sampler.

The sample ID number was assigned by using the following protocol: a four-letter code unique to the site, followed by the site visit number (e.g., “01” for pre-treatment, “02” for treatment, or “03” for one-week post-treatment), followed by the time since the application

(e.g., “pre” for the baseline sample, the number of hours since the application for the treatment sample, or “1w” for the one-week post-treatment event).

Equipment Calibration

Temperature, electrical conductivity, salinity, and dissolved oxygen were measured in the field with a newly purchased (2022) portable YSI Xylem ProSolo (Yellow Springs Instruments Inc., Ohio, USA), pH was measured with a newly purchased (2023) HM digital waterproof pH meter (Hanna Instruments), and turbidity was measured with an Oakton T-100. To assure accurate and reliable measurements, all three instruments were calibrated, operated, and maintained in accordance with their manuals.

Field Data Sheets

At each sampling location, the sample ID number, the time of the sampling, the sample depth, and the water temperature, pH, dissolved oxygen, conductivity, and salinity measurements were entered on a Field Data Collection Form (FDCF, **Appendix II**). Also recorded on the FDCF was site information including the site ID number, the station location (application point, upstream, downstream), station type (reference, treated), wind conditions, tidal cycle, water color, and the type of herbicide and surfactant utilized. Any other unusual conditions or concerns were noted, and any fish, birds, or other wildlife present at the point were recorded. The FDCFs were dated and numbered consecutively for each site on that date. Upon return to the office, the data were entered into an electronic spreadsheet for processing, and the FDCFs were compiled into a data log and kept permanently in the office.

Sample Shipment

Following collection, water samples were stored on ice packs and shipped for priority overnight delivery to the laboratory. ISP continued to utilize the Pacific Agricultural Laboratory in Sherwood, Oregon due to their consistent fulfillment of their contract requirements since 2010. In addition, pursuant to the requirements of the new General Permit from 2013, PAL underwent an audit and subsequent certification as an environmental testing laboratory by the California Department of Public Health.

If samples were not shipped until the following day, they were stored in a refrigerator and subsequently transferred back into a cooler with ice packs for shipping. Samples were not shipped on Fridays because they would not be received by the lab until the following Monday and the appropriate temperature could not be maintained.

Sample Analysis

The samples were analyzed within the appropriate holding times for imazapyr (extracted within seven days, analyzed within 21 days of extraction). Results are reported as parts per billion (ppb), equivalent to $\mu\text{g/L}$ (micrograms per liter). The analytical method used for imazapyr is EPA 8321B in which the extracts are analyzed using liquid chromatography with mass spectroscopy (LC/MS/MS) detection, with a Limit of Quantitation (LOQ) of 0.02 ppb (the minimum detectable level of the instrument) and Reporting Limit (RL) of 0.05 ppb. The lab ran one blank each time it conducted an analysis (minimum of one sample tested per batch, maximum of three). Results are submitted to the San Francisco Bay State and Regional Water Quality Control Boards in this annual report and placed on the ISP’s website for public viewing.

Lab QC & Data Quality Indicators

The contracted analytical laboratory (“lab”) is required to provide a Quality Assurance Plan (“QAP”) that meets U.S. EPA standards prior to initiating analysis (Pacific Agricultural Laboratory QA documents are attached as **Appendix VI**). The lab plan specifies the method of analysis to be used and describes any variations from standard protocol. The WQMM and ISP Director both reviewed the lab QAPs and determined that they were adequate. The data quality indicators (DQIs) established for the lab are listed in **Table 1**.

Table 1. Minimum Data Quality Indicators (DQIs) for an ISP-contracted Laboratory

<i>Criteria</i>	<i>Method</i>	<i>Indicator Goal</i>
Accuracy of measurement	Analyze matrix spikes and spike duplicates	1 matrix spike per 10 samples (10%) > 65% @ 2.0 µg/L
Agreement between measurements	Analyze lab duplicates and/or matrix spike duplicates	Relative percent difference < 25%
Completeness	Percent of usable data (completed/submitted)	95% return
Comparability of results	Standard reporting units Use of standardized analysis methods	All data reported in micrograms per liter (µg/L)/parts per billion (ppb) Standard method used if possible, any modifications identified, described, and supported.
Detection Limits (imazapyr, EPA 8321B)	Method detection limit Lab reporting limit	MDL ≤/ = 0.02 ppb LRL ≤/ = 0.05 ppb

4. 2024 *Spartina* Treatment and Water Quality Monitoring

4.1 Summary of 2024 Herbicide Applications

ISP partners utilized herbicide at 150 sites during the 2024 Treatment Season, with one site monitored for imazapyr in the adjacent receiving water pursuant to the most recent General NPDES Permit requirements. **Table 2** provides the site monitored, treatment date, and application method for 2024, while **Appendix V** provides the full list of treatment sites around the Estuary, the coordinates of site centroids, and the amount of herbicide applied by Coalition partners in 2024. **Appendix VII** provides maps showing the location of treatment sites for each ISP Coalition partner (“discharger”).

Table 2. Water Quality Monitoring Site for the 2024 Treatment Season

Site	Site Number	Marsh Type	Treatment Date	Application
Pinole Creek Marsh	22f	I (tidal marsh)	10/14/2024	Imazapyr – Backpack

Low-pressure backpack sprayer application was the herbicide delivery system utilized to treat hybrid *Spartina* at Pinole Creek Marsh in 2024, including some larger patches that have persisted out on the soft mudflats. The reliance on spot treatment methods reflects the significant progress ISP Coalition partners have made in reducing the non-native *Spartina* infestation around the Estuary.

4.2 Herbicide Levels in the Water at Sampled Treatment Site

ISP contracted with Pacific Agricultural Laboratories (PAL) again in 2024. No water samples were broken in shipment to PAL in 2024 and none were misplaced by FedEx.

Table 3. Herbicide Concentrations in Adjacent Surface Water for 2024 *Spartina* Treatment (ND = not detected at 0.02 ppb LOQ)

Site	Herbicide Concentration (ppb = µg/L)			Application
	Pre-Treatment	Treatment	One-Week Post	
Pinole Creek Marsh	0.04	0.18	0.11	Imazapyr – Backpack

Table 3 shows the imazapyr levels at the one site monitored for this herbicide in 2024, the marsh at the mouth of Pinole Creek. The lab reported an imazapyr concentration of 0.04 ppb was detected in the pre-treatment sample (ND). In the experience of the ISP, it is not uncommon for a very low level of imazapyr to be detected prior to *Spartina* treatment because this herbicide is widely used for ground clearing in residential and commercial landscaping higher in the watersheds, providing a non-point source around the Estuary. Pinole Creek Marsh is located downstream of several communities with tens of thousands of residents and numerous commercial enterprises.

Treatment event monitoring reported an imazapyr concentration of 0.18 ppb as the tide waters returned to the site. The one-week post-treatment sample from Pinole Creek Marsh reported an imazapyr concentration of 0.11 ppb in the Estuary water. The analytical reports from the lab are provided in **Appendix IV**.

Figure 1. Shoreline infestation of hybrid *Spartina alterniflora* amongst the native cordgrass fringe at the water quality sampling location at the mouth of Pinole Creek after imazapyr treatment

4.3 Conventional Water Quality Parameters at Treatment Site

Table 4 lists the data on the conventional parameters (water temperature, dissolved oxygen, pH, conductivity, salinity, and turbidity) collected at Pinole Creek Marsh in 2024.

Table 4. Conventional Water Quality Parameters Measured at 2024 Events

Site	Water Temp (C)			DO (mg/L)			pH			Conductivity (mS)			Salinity (ppt)			Turbidity (NTU)		
	Pre	Treat	Post	Pre	Treat	Post	Pre	Treat	Post	Pre	Treat	Post	Pre	Treat	Post	Pre	Treat	Post
Pinole Creek Marsh	20.8	18.4	18.2	8.4	8.0	8.4	7.8	8.0	7.7	35.0	33.8	34.0	24.3	24.7	25.0	58.9	26.4	58.1

The mean water temperature over all three sampling events was 19.1°C. Dissolved oxygen (DO) averaged 8.3 mg/L but varied little across all sampling events. The pH of the Estuary water averaged 7.8 and did not vary greatly across the three samples. Conductivity averaged 34.3 mS/cm over the three sampling events, within a very narrow range from 33.8 mS/cm to a maximum of 35.0 mS/cm. Salinity averaged 24.7 ppt, ranging from 24.3 ppt to 25.0 ppt. Finally, turbidity averaged 47.8 NTU over the three sampling events, ranging from 26.4 NTU to 58.9 NTU on the incoming tide.

5. Toxicology

Although there are currently no State or U.S. EPA-based numeric objectives or criteria for imazapyr, one can compare the post-treatment levels to the LC₅₀ (defined as the lowest tested concentration of a chemical that was lethal to 50% of test organisms in a laboratory experiment) for various species of wildlife to determine whether the sample concentration

should be a cause of concern for a given species or the trophic interactions of the estuarine ecosystem. At this point in the eradication, ISP Coalition partners normally apply imazapyr by spot treatment at the FIFRA label rate of 96 oz/A, equivalent to 680 grams 'acid equivalent' per acre (e.g., a tank mix of 3 g/L for 60 gal/A). A sample was submitted to Pacific Agricultural Laboratory by the ISP in 2010 straight from a hand-mixed tank that was to be applied at 25 gal/A and the lab reported it contained an appropriate concentration of 3.6 g/L.

The ISP imazapyr sample from the receiving waters from the 2024 treatment event was 0.18 ppb collected shortly after treatment, equivalent to 0.0002 mg/L. Grue (cited in Entrix 2003) reported a 96-hr LC₅₀ for juvenile rainbow trout of 23,336 mg/L and King *et al.* (2004) affirmed that level with their results of 22,305 mg/L. These lethal levels are orders of magnitude greater than the ISP's treatment sample from the 2024 treatment season, far below any level of concern. These LC₅₀ values in the literature for fish are obviously far higher concentrations than even the actual tank mix being applied to the target *Spartina*, not to mention the ecologically relevant residual concentration that may be found in adjacent surface water after a *Spartina* treatment event.

A survey of the available literature on imazapyr by Leson & Associates (2005) includes studies with various fish species [bluegill sunfish (*Lepomis macrochirus*), rainbow trout (*Oncorhynchus mykiss*), channel catfish (*Ictalurus punctatus*), fathead minnow (*Pimephales promelas*), Atlantic silverside (*Menidia menidia*), Nile tilapia (*Tilapia nilotica*), and silver barb (*Barbus genionotus*)] exposed to both the technical grade imazapyr as well as tank mixes with surfactants (Hasten® and Agri-Dex®). Hasten® is the pre-cursor to the Competitor® product that the ISP partners occasionally still use and therefore can serve well for comparison. As expected, the 96-hour LC₅₀ was lower when surfactants are included, and some fish species are more sensitive than the previously reported rainbow trout that are the standard for EPA fish toxicology evaluation. However, the lowest lethal concentrations were in the range of 100 mg/L, as compared with the ISP's 2024 measured treatment concentration of 0.0002 mg/L, representing orders of magnitude difference. In addition, with this relatively low observed environmental concentration, salt marsh birds and mammals are at very low risk from the herbicide treatment because even the lowest no-observable-effect-level (NOEL) reported from an 18-week dietary study on mallards was ≈ 200 mg/kg of body weight (b.w.); levels for rats were in the 2,000-10,000 mg/kg b.w. range. Either of these representative wildlife species would have to ingest many liters of treated water to reach the reported NOEL, and many more liters beyond that to reach the lethal level. This is obviously a very unlikely scenario, especially with the expected rapid excretion of imazapyr documented in the literature potentially compensating for any incidental ingestion.

These imazapyr levels may also be compared to published toxicity data for aquatic invertebrates; these organisms can be more sensitive in general than the fish species reported above. Mangels & Ritter (2000) reported the no-observable-effect concentration (NOEC) for imazapyr for the Eastern oyster (*Crassostrea virginica*) was >132 mg/L (the highest dose tested). Manning (1989) found the 21-day NOEC for the freshwater flea (*Daphnia magna*) was 97.1 mg/L. Again, comparing these values to the ISP's 2024 measured post-treatment concentration of 0.0002 mg/L shows orders of magnitude difference, well below any level of concern.

In addition, imazapyr is reported to have a low potential for bioaccumulation and is therefore not expected to adversely impact predators that feed on exposed aquatic invertebrates.

Applications to invasive *Spartina* occur just once annually, with minor exceptions when late-season surveys find individual plants that were missed during the initial application which could still receive a follow-up treatment during the active growing season and before senescence stops the potential for translocation. With the herbicide applications occurring just once each year, any inhabitants of the tidal marsh ecosystem are only subjected to a single acute exposure and are not receiving chronic, prolonged exposure from hybrid *Spartina* management; this enhances the already-substantial buffer of safety described above in this survey of the toxicology literature.

6. Conclusion

The State Coastal Conservancy's Invasive *Spartina* Project successfully implemented their Water Quality Monitoring Plan at the required representative sample of their aquatic herbicide application sites around the San Francisco Estuary during the 2024 *Spartina* treatment season, in compliance with the Statewide General Permit and National Pollutant Discharge Elimination System (NPDES). The successful *Spartina* control achieved since 2005 has reduced the estuary-wide infestation by 98% from 805 net acres to 18.7 net acres by 2024. Much less herbicide is now necessary to complete the annual treatment than in the initial years of the project, and this success has also enabled ISP partners to shift away from broadcast applications over the historic *Spartina* monocultures down to spot applications from airboat and backpack. By 2024, the majority of ISP sites are treated simply by backpack or handheld sprayer as the only herbicide delivery system needed, and the ISP is completing the eradication of all infestations of *S. densiflora* around the Estuary with only manual removal after successful reductions with imazapyr in the initial years. Fifty-nine ISP sites were at the zero-detection level in 2024, showing continued progress towards the goal of functional eradication.

The imazapyr sampling conducted immediately after *Spartina* treatment has consistently found that any concentrations detected in the receiving waters are two to four orders of magnitude below those reported in the toxicology literature as a concern to humans or the animals that inhabit the associated tidal marsh system, including the benthic invertebrates so fundamental to the tidal marsh food web. The most recent General Permit established an imazapyr Monitoring Trigger of 11.2 mg/L; this is equivalent to 11,200 ppb. ISP's maximum measured imazapyr concentration in 2024 was 0.18 ppb from the treatment event, more than 11,000 ppb below the Monitoring Trigger.

The one-week post-treatment sampling results are also consistent with the published literature that have found imazapyr is short-lived in an estuarine environment. In 2024, the imazapyr concentration measured one week after treatment was 0.11 ppb, representing a reduction of 39% (the four-year mean reduction reported from 2007-2010 at all monitored ISP sites was 95.8%). With the rapid degradation of this herbicide in the tidal environment, as measured by the imazapyr concentration in the water at the site one week after treatment, it is anticipated that sites that still had measurable concentrations at that point would likely be below detectable levels within a short time after that third sample.

Quality Assurance Plan for Pacific Agricultural Laboratory

Invasive *Spartina* Project 2024 Water Quality Monitoring Report

Extraction of Imidazolinone Herbicides in Water

1.0 Scope and Application

1.1 This procedure describes the extraction of imidazolinone herbicides from aqueous samples. This method is applicable to all types of water including, but not limited to, drinking water, storm water, surface water, and groundwater.

2.0 Summary of Method

2.1 A 500mL aliquot of sample is acidified to pH 2 and 12.5g sodium chloride is added. Sample is shaken in a separatory funnel with three 50mL portions of dichloromethane. Organic layers are drained [**through acidified sodium sulfate**] into a round bottom flask, and concentrated by rotary evaporation (SOP-AM-027).

3.0 Interferences

3.1 Potential interferences may include contamination from glassware and solvents, and co-extracted materials from the sample matrix. Care must be taken to avoid and/or minimize these potential interferences.

4.0 Sample Handling and Preservation

- 4.1 Samples should be taken in 1-L amber glass bottles with a PTFE lined cap.
- 4.2 Samples are taken at neutral pH, and stored at 4°C prior to extraction.
- 4.3 All water samples shall be extracted within seven (7) days of sampling.

5.0 Apparatus and Instrumentation

- 5.1 1000 mL glass separatory funnel
- 5.2 500 mL graduated cylinder
- 5.3 600 mL beaker
- 5.4 250 mL round bottom flask
- 5.5 Large glass funnel
- 5.6 pH meter
- 5.7 Top-loading balance, accurate to ± 0.01 g
- 5.8 Magnetic stir bar
- 5.9 Magnetic stir plate
- 5.10 Rotary evaporator, Rotavap; Yamato RE50

6.0 Reagents and Supplies

- 6.1 Organic-free water, DI H₂O
- 6.2 Methanol (MeOH) w/0.5% Formic Acid
- 6.3 Pesticide-grade Dichloromethane, DCM
- 6.4 6 N Hydrochloric Acid, HCl
- 6.5 Sodium chloride, ACS grade
- 6.6 Glass beads
- 6.7 **[Glass wool]**
- 6.8 **[Acidified sodium sulfate, Na₂SO₄]**

7.0 Procedure

- 7.1 For each sample, the necessary glassware items (separatory funnel, 600 mL beaker, and flat-bottom flask) are obtained, rinsed with Dichloromethane if necessary, and labeled with sample number. Beakers contain a magnetic stir bar, and two glass beads are added to each flat-bottom flask. Using a graduated cylinder, measure 500 mL of organic-

- free water for QC and transfer to a beaker with a stir bar. Likewise, measure and transfer 500 mL of sample into a beaker with a stir bar.
- 7.2 **[Sodium sulfate funnels are prepared by placing a small plug of glass wool into a glass powder funnel, to which ~25g acidified Sodium Sulfate is added. Funnels are rinsed with ~10mL DCM, and solvent is drained into waste. A funnel is placed on each labeled collection flask.]**
- 7.3 Using a 500 mL graduated cylinder, a 500 mL aliquot of sample is measured and transferred to the labeled 600 mL beaker.
- 7.4 Method Blank (BLK) consists of 500 mL deionized water in a 600mL beaker. This sample will be the negative control (QC) for the analysis.
- 7.5 Lab Control Sample/Lab Control Sample Duplicate (LCS/LCSD) each consist of 500 mL DI water in a 600mL beaker. Project specific spike compounds are added to each, and the standard log number and spike volume are recorded on extraction bench sheet. These samples will be the positive control (QC) for the analysis.
- 7.6 The pH of each sample and QC is adjusted to 2.0 by dropwise addition of 6N hydrochloric acid.
- 7.7 12.5 g of sodium chloride is added to each beaker, stirring until salt is completely dissolved.
- 7.8 The contents of each beaker are transferred into the appropriately labeled separatory funnel. Samples and QC are extracted by shaking three times with 50mL DCM. The lower (DCM) layers are drained **[through the acidified sodium sulfate funnel]** into the corresponding flat-bottom round flask.
- 7.9 **[After all solvent is collected, Na₂SO₄ funnels are rinsed with ~20mL Dichloromethane, to optimize recovery of analytes.]**
- 7.10 Extracts are concentrated to ~0.5 mL using rotary evaporation (SOP-AM-027), and remaining solvent is evaporated to dryness under a steady stream of nitrogen gas.

- 7.11 Extract is transferred to labeled culture tubes as per SOP-AM-XXX (Rotavap) using MeOH w/0.5% Formic acid as final solvent. Final volume is 2mL for most Imidazolinone extractions.
- 7.12 Extracts should be stored in refrigerator until analysis.

8.0 Calculations

- 8.1 N/A

9.0 Quality Control

- 9.1 At a minimum, batch QC will include a method blank (MB), and a Laboratory Control Sample/Laboratory Control Sample Duplicate (LCS/LCSD). Additional QC will be performed if there are project and/or method specific requirements. An extraction batch consists of a batch of 20 consecutive samples extracted within 7 days.
- 9.2 Spike recoveries are calculated after analysis to evaluate extraction efficiency.

10.0 Reporting

- 10.1 N/A

11.0 References

- 11.1 American Cyanamid Method 2261
- 11.2 American Cyanamid Method M1900

Imidazolinone Herbicides in Water by EPA 8321B

1.0 Scope and Application

- 1.1 This procedure is used to determine the concentrations of Imidazolinone herbicides in liquid matrices.

2.0 Summary of Method

- 2.1 A measured volume of sample is extracted using AM-033, Extraction of Imidazolinone Herbicides in Water.
- 2.2 Extracts are analyzed using liquid chromatography with mass spectroscopy (LC/MS) detection.

3.0 Interferences

- 3.1 Potential interferences may include contaminated solvents and extraction glassware, dirty chromatographic equipment, and co-extracted materials from the sample matrix. Care must be taken to avoid and/or minimize these interferences.

4.0 Sample Handling and Preservation

- 4.1 Store samples at 4°C out of direct sunlight. Water samples should be extracted within 7 days of sampling and analyzed within 40 days of extraction
- 4.2 Personal protection measures should be taken while handling solvents and samples.

5.0 Apparatus and Instrumentation

- 5.1 Analytical balance, Sartorius model CP124S, accurate to 0.0001g.
Calibration of balance shall be checked daily (SOP EQ-001).
- 5.2 N-EVAP evaporation manifold with heated water bath
- 5.3 HPLC System
 - 5.3.1 Agilent 1100 HPLC system equipped with binary pump, autosampler, solvent degasser, and single quadrupole mass spectrometer.
 - 5.3.2 Agilent Chemstation software
 - 5.3.3 Analytical Column – C18 reverse phase column, 100mm x 3.0mm ID, 2.5 µm particle size, Agilent Zorbax SB-C18 or equivalent.

6.0 Reagents and Supplies

- 6.1 Organic-free reagent water
- 6.2 Methanol, Chemsolve, HPLC Grade
- 6.3 Acetonitrile (ACN), Chemsolve, HPLC Grade
- 6.4 Formic Acid, EMD, ACS Grade
- 6.5 Luer lock tipped syringe
- 6.6 Screw capped tubes with Teflon lined lids
- 6.7 13mm 45 µm nylon syringe filters
- 6.8 Auto sampler vials with PTFE lined caps
- 6.9 Volumetric flasks, class A
- 6.10 Gas tight syringes with PTFE tipped plungers
- 6.11 HPLC/MS Tuning Standard – Agilent ES Tuning Mix G2421A

7.0 Procedures

- 7.1 Sample Extraction:
 - 7.1.1 Extract waters via the procedure outlined in Pacific Agricultural Laboratory SOP AM-033 “Extraction of Imidazolinone Herbicides in Water”.
 - 7.1.2 Store extracts in refrigerator until analysis.
- 7.2 Solvent exchange of water extracts:
 - 7.2.1 Transfer a 1 ml aliquot of the sample extract to a culture tube. Mark the meniscus of the liquid in the tube.
 - 7.2.2 Evaporate the solvent under a steady stream of nitrogen using the N-Evap evaporation manifold.
 - 7.2.3 Reconstitute the extract as follows: add 500 uL methanol, then 500 uL Mobile Phase A (95% organic free water, 5% ACN, 0.05% formic acid).
 - 7.2.4 Filter the sample extract into an autosampler vial through a 45 µm 13 mm syringe filter using a luer tipped syringe.
 - 7.2.5 Cap the vial and label with appropriate moniker.
- 7.3 Preparation of HPLC mobile phase:
 - 7.3.1 The mobile phase is contained in two reservoirs, one containing the aqueous portion (Mobile Phase A) and one containing the organic(Mobile Phase B) portion.
 - 7.3.2 Prepare Mobile Phase A by combining 950 mL of organic free water, 50 mL ACN, and 0.5 mL formic acid.
 - 7.3.3 Prepare Mobile Phase B by combining 950 mL of ACN, 50 mL organic free water, and 0.5 mL formic acid.
- 7.4 Chromatographic conditions:
 - 7.4.1 Flow rate: 0.40 mL/minute
 - 7.4.2 Injection volume: 10 ul
 - 7.4.3 Column Temperature: 45 °C

7.4.4 Solvent Gradient:

<u>Time</u>	<u>%A</u>	<u>%B</u>
0.0	80	20
1.5	80	20
8.0	30	70
10	30	70

7.4.5 Re-equilibration time: 3 minutes, 80% A/20% B

7.5 Mass Spectrometer Conditions:

7.5.1 Ionization Mode: API-Electrospray

7.5.2 Drying Gas: N₂, 11.0 L/min, 250 °C

7.5.3 Nebulizer Pressure: 30 psig

7.5.4 Capillary Voltage: 1500 V

7.6 Mass Spectrometer Detector settings:

7.6.1 Settings for use in MS data acquisition (SIM ions and fragmentor voltages) vary by analyte and are displayed in Table 2 of the Appendix (12.2).

7.7 If the peak areas of the sample signals exceed the calibration range of the system, dilute the extract as necessary and reanalyze the diluted extract.

7.8 Calibration:

7.8.1 Electrospray MS System: The MS system is calibrated for accurate mass assignment, sensitivity, and resolution using the Agilent ES Tuning Mix G2421A. The following masses are calibrated in positive and negative ionization modes:

MASS	POSITIVE	NEGATIVE
1	118.09	112.99
2	322.05	431.98
3	622.03	601.98
4	922.01	1033.99
5	1521.97	1633.95

Tune parameters are adjusted to ensure ions are present at each of the masses with counts >50000 and peak widths within the range of 0.60 – 0.70 amu.

7.8.2 Stock Standards: Individual analyte stock standards are made at concentrations between 500-1000 µg/ml by transferring 25-50 mg neat standard to a 50 mL class A volumetric flask, dissolving the neat standard in acetonitrile or methanol, and diluting to the mark with acetonitrile or methanol. Stock standards prepared from neat standards may be used for a maximum of two years. Alternatively, a solution containing 1000 µg/ml of analyte may be obtained from ChemService or other reputable manufacturer and used as a stock standard. In this case, the stock standard may be used until the expiration date provided by the manufacturer.

7.9.3 Working Standards: A 10 µg/ml working standard is made by transferring appropriate amounts, depending on initial concentrations, of stock standards to a 10 mL class A volumetric flask and diluting to the mark with methanol or acetonitrile. The

amount of stock standard to transfer will range between 100-200 μL and is calculated using the formula:

$$\text{Amt. Stock Std.}(\mu\text{L}) = \frac{[\text{Final Conc. (10}\mu\text{g/ml)}] \times [\text{Final Vol. (10ml)}]}{\text{Initial Stock Conc. (}\mu\text{g}/\mu\text{L)}}$$

The working standard solution is transferred to an appropriately labeled screw cap tube and may be used for a maximum of one year.

- 7.9.4 Preparation of external standard calibration curve: an appropriate aliquot of the working standards are added to an autosampler vial and diluted to 1 ml with Mobile Phase A. A minimum of 5 standards are prepared at the following suggested levels: 0.005 $\mu\text{g/ml}$, 0.010 $\mu\text{g/ml}$, 0.020 $\mu\text{g/ml}$, 0.05 $\mu\text{g/ml}$, and 0.10 $\mu\text{g/ml}$. The calibration range can be adjusted to meet expected levels in the samples. The calibration standards are prepared as follows:

Calibration level	Aliquot volume	Concentration of aliquot(s)	Volume of buffer	Final volume
100 ng/ml	100 μl	1000 ng/ml	900 μl	1.0 ml
50 ng/ml	50 μl	1000 ng/ml	950 μl	1.0 ml
20 ng/ml	200 μl	100 ng/ml	800 μl	1.0 ml
10 ng/ml	100 μl	100 ng/ml	900 μl	1.0 ml
5 ng/ml	50 μl	100 ng/ml	950 μl	1.0 ml

- 7.9.5 The system is calibrated prior to the injection of a set of sample extracts. After injecting a set of standards, a linear calibration curve is prepared. Exclude the origin as a point. The R value of the generated curve should be 0.99 or better. If the calibration fails to meet these criteria, the cause of the deviation should be rectified and the system recalibrated.

- 7.9.6 The calibration is verified by injecting a CCV at the mid point concentration of the calibration curve after no more than twenty

samples. If the response deviates by more than +/- 15% from the initial calibration, the system should be recalibrated and the samples bracketed by the either the initial calibration or the prior passing CCV and the failing CCV should be reanalyzed. If the CCV is >15% of initial calibration, the samples bracketed by the either the initial calibration or the prior passing CCV and the failing CCV can be used if the sample contains no detectable residues.

8.0 Calculations

8.1 Water Samples:

$$\frac{\text{amount f/curve (ng/ml)} \times \text{final volume (ml)} \times \text{dilution factor}}{\text{sample volume (ml)}} = \text{result (ug/liter, ppb)}$$

9.0 Quality Control

9.1 Initial Demonstration of Proficiency – the laboratory shall demonstrate initial proficiency with each sample preparation technique, by generating data of acceptable accuracy and precision for target analytes in a clean matrix. The laboratory must also repeat the demonstration whenever new staff is trained or significant changes in instrumentation are made.

9.1.1 Calculate the average recovery and the standard deviation of the recoveries of the four QC reference samples. Refer to Section 8.0 of EPA Method 8000 for procedures in evaluating method performance.

9.2 Method Reporting Limits (MDLs)

9.2.1 The MDL is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero and is determined from analysis of a sample in a given matrix type containing the analyte.

- 9.2.2 The extraction and analysis of seven replicates of a spiked sample determine the MDL.
- 9.2.3 Multiply the standard deviation of the seven replicate results by the one sided 99% t-statistic (3.14) to obtain the MDL for each analyte.
- 9.2.4 These results are kept on file and should be re-evaluated annually, when significant changes in instrumentation are made, or when new staff are added.
- 9.3 Sample Quality Control for Preparation and Analysis
- 9.3.1 The laboratory will have procedures for documenting the effect of matrix on method performance.
- 9.3.2 Water matrix – minimum QC samples shall include a method blank (MB), Laboratory Control Sample (LCS), and a Laboratory Control Sample Duplicate (LCSD). A matrix spike may be prepared and analyzed provided there is adequate sample.
- 9.4 QC Frequency – an analytical batch is defined as a set of no more than 20 samples extracted within 14 days. The QC frequency for each analytical batch is as follows:
- Method blank – 5%
 - Matrix Spike/Matrix Spike Duplicate – 5%
 - Laboratory Control Sample/Laboratory Control Sample Duplicate – 5%
- 9.4.1 In house method performance criteria for spike and surrogate compounds should be developed using guidance found in Section 8.0 of EPA Method 8000.
- 9.4.2 If the recovery data is outside acceptance limits, the samples should be re-extracted and/or the data flagged as necessary.

10.0 Reporting

10.1 If all QC criteria have been met, the data is then compiled and a report is generated, including sample raw analytical results and QC data, and submitted to the client.
